

NAME: ACQUAH JACKSON

REFERENCE: GILEAD CLINIC

PID NO: P36170021718

VID: 36170123986

Date of visit: 23/02/2018

Report reading date: 26/02/2018

AGE: 46 Years(s) Sex: male

Metropolis Healthcare (Ghana) Ltd.

Mantoux test

Negative (2)mm

Negative: 0-4 (10TU PPD)
Indeterminate: 5-9
Positive: > 10

INTERPRETATION:

- The Mantoux tuberculin skin test (TST) is the standard method of an intradermal injection of 0.1 ml of tuberculin purified protein derivative (PPD) into the inner surface of the forearm. The skin test reaction should be read between 48 and 72 hours after administration. A patient who does not return within 72 hours will need to be rescheduled for another skin test.
- The reaction is measured in millimeters of the induration (palpable, raised, hardened area or swelling) while erythema (redness) is excluded & not measured. The diameter of the indurated area is measured across the forearm (perpendicular to the long axis). An induration of 5 or more millimeters may be considered positive in HIV-infected persons, Persons who are immunosuppressed for other reasons (e.g., taking the equivalent of >15 mg/day of prednisone for 1 month or longer, taking TNF-a antagonists), patients with organ transplants.
- Positive mantoux test suggests delayed hypersensitivity reaction (type IV cell mediated immunity) to tuberculin protein, which in turn may be due to previous TB infection, BCG vaccination, exposure to atypical & nontuberculosis mycobacteria or Latent & Active TB, hence clinical correlation is necessary.
- False-negative reactions may be seen with the following Cutaneous anergy (inability to react to skin tests because of a weakened immune system), recent TB infection (within 8-10 weeks of exposure), young age (less than 6 months), viral infections (like measles, varicella, influenza, EBV), very old TB infection (many years) resulting in boosted reaction, Overwhelming TB disease like miliary TB.
