NAME: KWEKU ATIA

AGE: 34YRS

DATE: 3RD OCTOBER, 2018

Hx : CHRONIC KIDNEY Dx. SWELLING OF LT UPPER LIMB

VENOUS DOPPLER U.S.G. REPORT OF LEFT UPPER LIMB

Color Doppler interrogation also indicates, typical venous flow in subclavian, axillary, brachial, ulna and radial veins which also flatten on Valsalva maneuver in left upper limb with no sign of reversal flow to suggest valve incompetence.

They augment by compressing distal to each of the vein being assessed with the said veins demonstrating patency and show complete wall-to-wall compressibility with good colour and spectral properties devoid of any deep vein thrombosis or wall abnormalities.

No enlarged lymph nodes noted in the axillary region or edema seen in the left upper limb.

IMPRESSION: Findings in keeping with

1. Normal venous Doppler ultrasound scan of left upper limb.
2. No cellulitis of left upper limb.

Authorized signature.....
